1. INTRODUCTION

ESWNMAN Pty Ltd (ESWNMAN) was commissioned by Mr Elie Trassieh c/- Inhaus Designs to undertake a geotechnical investigation at No. 12 Grove Street, Earlwood, NSW 2206. The fieldwork was completed on 26th June 2025 by ESWNMAN staff under the supervision of an experienced Geotechnical Engineer.

The purpose of geotechnical investigation was to assess the feasibility of site in geotechnical prospective for proposed residential development.

This report presents results of investigation & in-situ tests, interpretation & assessments, and provides comments on geotechnical related issues and recommendations.

1.1 Available Information

The following design information was provided to ESWNMAN prior to the fieldwork:

• Architectural drawings titled "12 Grove Street, Earlwood, NSW" prepared by Inhaus Designs, referenced Project No. 2543, including drawing nos. INHAUS-00 to INHAUS-12 inclusive, Revision C and dated 17th June 2025.

1.2 Proposed Development

Based on design information provided as referenced in Section 1.1, the proposed development will comprise the demolition of existing structures and construction of proposed two storey semi-detached dwellings above basement level.

The design plans indicate approximate excavation between 2.4m and 3.0m deep for basement level would be required during construction. An approximate setback of 0.9m was proposed for basement level from site northern and southern side boundaries.

In addition, the following excavation, minor cut/fill and earthworks are likely also required:

- Excavation of driveway ramp from street entry to basement level;
- Excavation of RWT and pump out pits;
- Excavation within structural footing areas (such as, pad/strip footings or piles);
- Trench excavation/backfilling for installation of water/sewer/stormwater pipes;
- Subgrade preparation for pavement and footpath; and
- Landscaping.

1.3 Scope of Work

The geotechnical investigation was undertaken by an experienced Geotechnical Engineer from ESWNMAN, including the following:

- Desktop study on local geology and our in-house dataset near the subject site;
- Collection and review of Before-You-Dig-Australia (BYDA) plans;
- A site walkover to assess site accessibility and surface conditions, identify relevant site features, and nominate borehole and testing locations;
- Augering of boreholes to check thickness of fill and property of natural soils;
- Performing of Dynamic Cone Penetrometer (DCP) Test to assess strength of soils with depth and rock profile;
- Geotechnical logging of materials retrieved from boreholes by an experienced Geotechnical Engineer;
- Reinstatement of site upon completion of site work;
- Interpretation of investigation data obtained; and
- Preparation of a geotechnical report.

The approximate locations of boreholes and DCP test completed are shown on Figure 1 – "Site location Plan" as included in Appendix A of this report.

2. SITE DESCRIPTION

The site is located within the Canterbury-Bankstown Council area, approximately 9.4km to the southwest of Sydney CBD, 560m to the east of Cup and Saucer Creek and 620m to the south of Cooks River.

The site is a rectangular-shaped land, identified as Lot 10, Section 8 in Deposited Plan(DP)32036, with an approximate area of 393.8m². At time of fieldwork, the site was occupied by a one & two storey clad residence.

Based on our observations during a site walkover, the existing ground surface was generally flat and sloping slightly towards the northwest.

Selected site photographs recorded during site investigation are provided in Appendix B.

3. LOCAL GEOLOGY

Reference to the Sydney 1:100,000 Geological Series Sheet 9130 (Edition 1), dated 1983, by the Geological Survey of New South Wales, Department of Mineral Resources, indicates the site is located within an area underlain by Triassic Age Ashfield Shale

Formation (Rwa) of the Wianamatta Group. The Ashfield Shale is described as "Black to dark grey shale and laminite".

The map also shows the site is very close to another geological unit, i.e. Hawkesbury Sandstone (Rh), which consists of "Medium to coarse-grained quartz sandstone, very minor shale and laminite lenses".

Results of the investigation provided in Section 5.2 confirmed the published geology.

4. METHODOLOGY OF INVESTIGATION

4.1 Pre-fieldwork

Prior to the commencement of fieldwork, a desktop study on local geology and our inhouse dataset near the subject site was undertaken.

BYDA underground services search was conducted with plans reviewed prior to the mobilisation and in-situ tests.

4.2 Borehole Drilling

During fieldwork, portable investigation involved augering of boreholes was completed to check thickness of fill and property of natural soils using a hand operated equipment assisted with in-situ tests.

The borehole locations are shown on Figure 1 – "Site Location Plan" attached in Appendix A. Engineering logs of boreholes processed using Bentley gINT software together with borehole explanatory notes are presented in Appendix C.

4.3 Dynamic Cone Penetrometer (DCP) Test

The Dynamic Cone Penetrometer (DCP) Test involves hammering cone tipped rods using a standard weight and drop height. The number of blows required to penetrate each 100 mm is recorded (Reference 2). The DCP test is used to assess in-situ strength of undisturbed soil and/or compacted materials. The penetration rate of the 9-kg DCP can be used to estimate in-situ CBR (California Bearing Ratio) and to identify strata thickness and other material characteristics.

A total of four(4) DCP tests, identified as DCPs 1 to 4 inclusive, were completed during site investigation, to assess the strength of soils with depth and rock profile. DCP tests reached refusal depth or bounce of DCP hammer occurred approximately at 1.7m, 1.2m,

1.5m and 1.3m below the existing ground level (BGL) at location of DCPs 1 to 4 respectively

The location of DCP test is shown on Figure 1 attached in Appendix A. The record of DCP test results is presented in Appendix D.

All fieldwork was supervised on a full time basis by an experienced Geotechnical Engineer who was responsible for nominating locations of boreholes and DCP tests, preparing field engineering logs of subsurface strata encountered in accordance with AS 1726 for Geotechnical Site Investigation (Reference 1), conducting in-situ tests and taking photos.

5. RESULTS OF INVESTIGATION

5.1 Surface Conditions

At time of fieldwork, apart from existing dwelling, a garage, a carport, a shed, paved driveway and surface, the remainder of outdoor areas was covered with grass and lawn.

5.2 Subsurface Conditions

Based on borehole information and interpreted results of DCP test, the subsurface conditions encountered at testing locations consisted of the following:

- Fill (Unit 1): Clayey SAND, fine grained, grey & brown, some topsoil, trace gravel, mostly poorly compacted, approximately extending to 1.0m, 0.5m, 0.5m and 0.3m BGL at location of BH1 to BH4 respectively; overlying
- **Residual Soils** (Unit 2): Clayey SAND, medium grained, brown & light grey, moist, varying from "medium dense" to "very dense", some sandy CLAY, approximately extending to inferred top of rock below 1.7m, 1.2m, 1.5m and 1.3m BGL at location of DCP1 and DCP4 respectively; overlying
- Weathered Sandstone/Shale (Unit 3): Class V-IV SANDSTONE, some SHALE and laminite, extremely weathered, low and medium strength, based on interpreted results of DCP tests and local geology. Local geological map indicates the site is located within the transition of Hawkesbury Sandstone(Rh) and Ashfield Shale(Rwa) as indicated in Section 3. Classification of rock was carried out in accordance with the guidelines provided by Pells et al (Reference 9).

Subsurface conditions described above are also summarised in Table 1 overleaf.

Geotechnical Unit and Description		Inferred Depth at Top of Unit (m, BGL)			
		BH1/ DCP1	BH2/ DCP2	BH3/ DCP3	BH4/ DCP4
Fill (Unit 1)	Clayey SAND, poorly compacted	0	0	0	0
Residual Soils (Unit 2)	Clayey SAND, medium dense to very dense, some hard sandy CLAY	1.0	0.5	0.5	0.3
Weathered Sandstone (Unit 3)	Class V-IV SANDSTONE, some SHALE and laminite, low and medium strength	>1.7	>1.2	>1.5	>1.3

Table 1 - Subsurface Conditions at Testing Locations

5.3 Groundwater

No groundwater was encountered during augering of any boreholes. No indication of water seepage/inflow and no wet soil materials were observed on DCP tools when DCP accessories were extracted onto ground surface upon completion of DCP tests.

6. GEOTECHNICAL ASSESSMENTS

The main geotechnical aspects associated with proposed development are assessed to include the following:

- Site classifications;
- Excavation conditions;
- Stability of excavation/shoring measures;
- Earth retaining structures;
- Foundations;
- Foundation/subgrade preparation;
- Earthworks and material use;
- Water/seepage management;
- Preliminary comments on pavement subgrade; and
- Excavation methods and vibration control measures.

The assessment of the listed above and recommendations for the proposed development are presented in the following sections.

6.1 Site Classifications

(a) Site reactivity classification

Based on the site soil profile, proposed development and the criteria specified in AS2870 (Reference 3), the site can be assessed as Class M - "Moderately reactive clay and silt

sites", which may experience moderate ground movement from moisture changes, provided that our recommendations in Section 6.5 are adopted during design and construction.

The above classification and footing recommendations are provided on the basis that the performance expectations set out in Appendix B of AS2870 are accepted.

Design, construction and maintenance of plumbing, ground drainage, protection of building perimeter, the garden, etc. should be carried out in accordance with CSIRO BTF18 (Reference 11) to avoid any water related problems or significant changes of moisture in building foundations, which may contribute to surface movement.

(b) Site earthquake classification

The results of geotechnical investigation indicate the presence of fill and residual soils, underlain by Class V Sandstone or stronger rock with some shale and laminite. In accordance with Australian Standard AS1170.4 (Reference 6), the site sub-soil may be classified as a "Shallow soil site" (Class C_e) for design of foundations and retaining walls embedded in the soils or a "Rock Site" (Class B_e) for design of foundations and retaining walls embedded in underlying rock. The Hazard Factor (Z) for Earlwood in accordance with AS1170.4 is considered to be 0.08.

6.2 Excavation Conditions

Based on proposed development as provided in Section 1.2, the approximate excavation between 2.4m and 3.0m deep for basement level would be required during construction. Other minor excavation likely required during construction may include the excavation of driveway ramp from street entry to basement area, pump out pit, structural footing areas (such as, pad/strip footings or piles), trench excavation/backfilling for installation of water/sewer/stormwater pipes, and landscaping.

The shoring wall should be constructed as per our recommendation in Section 6.3(b) and details in structural design drawings prior to any excavation along site boundaries.

Any fill and deleterious materials, including old footings/buried structures, concrete slabs, plant/tree roots, redundant services, timber/brick material, and sandstone boulders, are expected to be stripped and removed from development area to spoils.

The results of geotechnical investigation indicate majority of excavation for proposed buildings will likely be within Fill, Residual Soils and Weathered Sandstone/shale.

Excavation of soils (Unit 1 & Unit 2) and Class V Sandstone/shale (Unit 3) will be typically feasible using conventional earthmoving equipment. Heavy ripping and rock breaking equipment or vibratory rock breaking equipment is typically required for excavation in medium strength Class IV Sandstone or higher strength rock.

We assessed it is unlikely to encounter high strength shale during construction excavation. Nevertheless, if it is encountered by chance, the excavation should be carried out strictly in accordance with our recommendations provided in Section 6.9, in which excavation methodology, type of excavation plants and safe distance, and vibration control measures were recommended to minimise induced ground vibration.

Based on groundwater conditions in Section 5.3, we assessed construction excavation for proposed basement level and associated works will not encounter groundwater.

6.3 Stability of Excavation/Shoring Measures

(a) *Shallow Excavation* (i.e. <1.5m in Depth)

The excavations should be carried out in accordance with the 'NSW Government: Code of Practice – Excavation Work' (Reference 8).

Temporary excavations through the underlying soils to a maximum depth of 1.5m may be excavated using a safe excavation batter provided that:

- They do not encroach ZOI(Zone of Influence, defined as 45° angle of draw from nearest edge of footing underside) of any site or adjoining structures;
- They are barricaded when not in use;
- They are not left open for more than 24 hours;
- No surcharge loading is applied within 1.5m from edge of excavation/footings;
- No groundwater flows are encountered; and
- They are not used for access by a worker.

Where access is required for workers, the temporary excavation batters should be re-graded to no steeper than 2 Horizontal (H) to 1 Vertical (V) for soils or supported by suitable temporary shoring measures/formworks.

We recommend a permanent safe batter of 3H:1V or flatter can be adopted for soil materials within the site for re-battering and landscaping.

Any permanent excavation (or filling) greater than 0.6m in height should be retained by a retaining wall to be designed by a qualified Engineer based on the recommendation provided in Section 6.4.

(b) *Deep Excavations* (i.e. >1.5 m in Depth)

Any excavation batters in soils and/or rocks greater than 1.5 m in depth, the temporary safe batters for excavated slopes in Table 2 below can be adopted under dry conditions:

Geotechnical Unit ³	Maximum Batter Angle				
Geotechnical Unit	Temporary ²	Permanent			
Fill (Unit 1)	2.0H:1V	To be retained			
Residual Soils (Unit 2)	1.75H:1V	To be retained			
Class V Sandstone(Unit 3)	1H:2.5V to Sub-vertical, Self-supporting	Reinforced shotcrete or To be retained			

 Table 2 - Recommended Safe Excavation Batters¹

Notes:

¹ - Typical temporary batters of excavated slopes (Hoerner, 1990). Assume no surcharge on top of cut/excavation. Excavation using benching technique can be adopted.

 2 - Reinforced shotcrete with drainage, inclined/raking shores/braces or earth berms/formworks can be considered as temporary support/shoring measures for excavation over short period of time.

 3 – Approximate depth to top of unit refers to Table 1.

Based on proposed setbacks and approximate excavation depth provided in Section 1.2, we assessed excavation using temporary safe batters recommended in Table 2 would be typically feasible for majority excavation of proposed basement level away from side boundaries.

However, it may not be possible or impractical to use safe excavation batters in Table 2 for excavation along southern and northern side boundaries due to inadequate setback proposed or considerations of lateral ground movement and safe work in front of the excavation/cut. The following excavation support/shoring measure should be installed **prior to excavation**:

- Soldier pile wall shoring system; or
- Contiguous pile or a line of closely spaced piles (<1.0m spacing C.T.C.).

Other alternative shoring options and additional supports may be considered subject to the on-site assessment and approval by the project Structural and Geotechnical Engineers.

A dilapidation survey of adjoining properties, roads and public infrastructure should be carried out prior to the commencement of construction work.

During excavation, observations and recording on conditions of exposed faces, safe excavation batters and support/shoring measures adopted should be carried out by a Geotechnical Engineer.

Earth retention structures can be designed using the recommended parameters provided in Section 6.4.

If our recommendations on the above are adopted during design and construction, the construction of proposed development and excavation over a short and long term will have no impacts on adjoining properties, roads and public infrastructure.

6.4 Earth Retaining Structures

The earth retaining structure should be designed to withstand the applied lateral pressures of the subsurface layers, the surcharges in their zone of influence, including loading from existing structures, construction machinery, traffic and construction related activities. The design of retaining structures should also take into consideration hydrostatic pressures and lateral earthquake loads as appropriate. **Filter type geofabric should be considered to be installed between wall backfill area and surrounding soils** to avoid soil erosion and to prevent the fines from entering the wall drainage system.

The retaining wall design should be carried out in accordance with AS 4678 (Reference 7).

The recommended preliminary parameters for design of retaining structures are presented in Tables 3 and 4 below. The coefficients provided are based on drained conditions.

Geotechnical Unit	Unit Weight (kN/m ³)	Effective Cohesion c' (kPa)	Angle of Effective Internal Friction ∅ (degree)	$\begin{array}{c} Modulus \ of \\ Elasticity \\ (E_{s \ (h),} MPa) \end{array}$	Poisson's Ratio (v)
Fill (Unit 1)	17	0	30	10	0.35
Residual Soils (Unit 2)	18	0	33	30	0.35
Class V Sandstone(Unit 3)	24	50	34	100	0.20

 Table 3 - Preliminary Geotechnical Design Parameters for Retaining Walls

Geotechnical Unit	Coefficient of Active Lateral Earth Pressure (Ka)	Coefficient of Lateral Earth Pressure at Rest (Ko)	Coefficient of Passive Lateral Earth Pressure (Kp)		
Fill (Unit 1)	0.33	0.50	3.0		
Residual Soils (Unit 2)	0.29	0.46	3.4		
Class V Sandstone (Unit 3)	0.28	0.44	3.5		

The coefficients of lateral earth pressure should be verified by the project Structural Engineer prior to use in the design of retaining walls. Simplified calculations of lateral active (or at rest) and passive earth pressures can be carried out using Rankine's equation shown below:

 $Pa = K \gamma H - 2c\sqrt{K}$ For calculation of Lateral Active or At Rest Earth Pressure $Pp = K_p \gamma H + 2c\sqrt{K_p}$ For calculation of Passive Earth Pressure Where:

 P_a = Active (or at rest) Earth Pressure (kN/m²) P_p = Passive Earth Pressure (kN/m²) γ = Bulk density (kN/m³)K= Coefficient of Earth Pressure (Ka or Ko)Kp= Coefficient of Passive Earth PressureH= Retained height (m)c= Effective Cohesion (kN/m²)

6.5 Foundations

Results of geotechnical investigation and assessment indicate the ground conditions at this are suitable for proposed subdivision, semi-detached dwellings and associated works.

It is noted that after excavation of basement level to proposed FFL, the materials at bulk excavation level are likely predominately occupied by Unit 3 – "Class V Sandstone" with some shale and laminite. Therefore, we assessed a footing system consisting of **cast-in-situ reinforced concrete shallow foundations**, such as pad or strip footings under columns and walls, are applicable for the proposed structures within basement area; while for those structures proposed outside the footprint of basement area, **piers/piles founded** in Unit 3 – "Class V Sandstone" should be considered. Bored piles can be adopted.

Any other footing systems rather than recommended above are adopted during design and construction, the project geotechnical Engineer should be consulted for further advices.

Preliminary geotechnical capacities and parameters recommended for design of shallow and piled foundations are provided in Table 5 overleaf.

Geotechnical Unit	Allowable End Bearing Pressure ¹ (kPa)	Allowable Shaft Adhesion Compression ² (kPa)	Modulus of Elasticity (Es,v, MPa)
Fill (Unit 1)	N/A ³	N/A ³	15
Residual Soils (Unit 2)	150 (Shallow footings)	10	30
Class V Sandstone (Unit 3) ⁴	600 (Shallow footings/piles) ⁴	50	120

Note:

¹ Applying a multiplier of 3.0 for ultimate capacities.

 2 Shaft Adhesion applicable to piles only. Applying a multiplier of 0.5 for skin friction under tension.

 3 N/A, being excavated or Not Applicable or not recommended for supporting structures unless re-compacted.

⁴ Some SHALE and laminite.

Design of shallow and piled foundations should be carried out in accordance with Australian Standards AS2870 (Reference 3) and AS2159 (Reference 4) respectively.

To minimise the potential effects of differential settlement under the buildings loads, it is recommended all foundations of the proposed building should be founded on consistent materials of similar properties or rock of similar class.

Any water, debris, loose and wet materials should be removed from excavations prior to placement of reinforcement and pouring of concrete.

A Geotechnical Engineer should be engaged to inspect footing excavations and construction to ensure foundation bases have suitable materials with adequate bearing capacity, and to check the adequacy of footing embedment or pile socket length if **unexpected ground conditions** are encountered during construction excavation or a **geotechnical certificate** is required.

6.6 Foundation/Subgrade Preparation

For services pipes, slabs to partially or fully rely on soils underneath (existing fill or new fill), to achieve an allowable bearing capacity of 150kPa, the following can be adopted as a guidance:

- Excavate and re-compact existing Fill (Unit 1);
- Remove roots/timber and organic matters and oversized materials(if any);
- Level off the existing natural ground surface and provide proof rolling;
- Place fill materials (preferably granular materials) at loose layer of not exceeding 150mm in thickness for cohesive soils and 200mm for cohesionless materials;
- Densify the fill mechanically, using a suitable roller or compaction equipment;

• Repeat the above till proposed FLL is reached.

For compaction over a small area or inside a trench, a vibrating plate compactor is commonly used to compact and densify the subgrade/foundation areas.

The fill and compaction for different engineering purposes should be carried out in accordance with our recommendations provided in Section 6.7 below.

6.7 Earthworks and Material Use

The excavated materials from excavation are assessed to be generally suitable for landscaping provided they are free of any contaminants.

The suitability of site won materials or imported materials for engineering fill should be subject to satisfying the following criteria:

- The materials should be Virgin Excavated Natural Material (VNEM) (i.e. free of contaminants, deleterious or organic material), free of inclusions of >75mm in size, high plasticity material be removed and suitably conditioned to meet the design assumptions where fill material is proposed to be used.
- The materials should satisfy the Australian Standard AS 3798-2007 Guidelines on Earthworks for Commercial and Residential Developments (Reference 5).

The final surface levels of all excavation and filling areas should be compacted in order to achieve an adequate strength for subgrade.

As a guidance for fill construction, the following compaction targets can be adopted:

- Moisture content of $\pm 2\%$ of OMC (Optimal Moisture Content);
- Minimum density ratio of 100% of MDD (Maximum Dry Density) for filling within building/structural foundation areas;
- Minimum density ratio of 98% of MDD for filling surrounding the pipes within trenches or behind retaining walls (unless otherwise specified in design drawings);
- The loose thickness of layer should not exceed 150mm for cohesive soils and 200mm for cohesionless soils; and
- For the footpath and pavement areas, minimum density ratio of 95% of MDD for general fill and 98% for the subgrade to 0.5m depth.

Design and construction of earthworks should be carried out in accordance with Australian Standard AS 3798-2007 (Reference 5).

6.8 Water/seepage Management

The groundwater conditions and observations summarised in Section 5.3 indicate the construction excavation of proposed basement level will not encounter groundwater.

Based on our experience and observation of excavation in surrounding areas, it is possible that localised minor seepage/inflow may occur along interface between soils and underlying rock, fractures/defects in the rock, including apertures, joints or other natural defects within the underlying sandstone/shale, in particular, when it encounters an intense and prolonged rainfall event.

Nevertheless, it would be prudent at this stage to allow for precautionary drainage measures in the design and construction of the proposed development. As a guidance, the following measures can be considered during design and construction:

- Strip drains or drainage materials to be installed behind shoring/retaining walls.
- Collection trenches or pipes and pits connected to the building stormwater system. A stormwater storage tank and pump system may be required.
- A filter type geofabric membrane to be installed between the retaining wall and backfilling soils to prevent loss of fines from surrounding soils.
- "Sump and pump method" can be typically adopted for any stormwater/localised seepage occurs in foundation pit during intense and prolonged rainfall period.

6.9 Excavation Methods and Vibration Control Measures

For the proposed development, the excavation within rock will be required for lower part of proposed basement level, driveway ramp, pump out pit and footings.

Induced vibrations in structures adjacent to the excavation should not exceed a Peak Particle Velocity (PPV) of 10mm/sec for brick or unreinforced structures in good condition, 5mm/sec for residential and low rise buildings or 2mm/sec for historical or structures in sensitive conditions.

The majority of excavations will occur within soils (Unit 1 & Unit 2) with minor extremely low and low strength Class V Sandstone (Unit 3) with some shale and laminite. Since excavation of rock will likely occur at lower part of basement level and it is unlikely to encounter high strength rock within depth of excavation based on inspection observation of deep excavation at several sites in surrounding areas, we assessed the excavated induced ground vibration is negligible to very low.

Based on the subsurface conditions, the excavation equipment listed in Table 6 below can be adopted as a guidance during excavation of basement and other areas, including demolition of existing site structures.

Geotechnical Unit*	Likely Plant Requirements
Soils and Class V Sandstone/Class V-IV Shale	Buckets attached to large excavators or dozers, using "tiger teeth"
Class IV Sandstone/ Class III Shale	Medium size rock breaking hammer, ripper on 20 tonne excavator, large dozer or 30 tonne Excavator, Caterpillar D9 or larger
Class III Sandstone/ Class II Shale	Heavy rock breaking, hydraulic rock Hammers

 Table 6 – Preliminary Type of Typical Excavation Plant

Note: * Rock classification to be undertaken by a Geotechnical Engineer as per Pells et al (Reference 9). For excavation in rock, plant selection will depend on the proximity of neighbouring structures and their susceptibility to damage caused by vibration induced by excavation plant. In order to control vibrations to an acceptable limit, we recommend that small to medium rock hammers would be feasible in consideration of rock strength at this site and proximity to the adjoining buildings and infrastructure.

The propagation of vibrations at a site will depend on the plant used and the ground conditions, construction activities, and type of foundations of the structure receiving the vibrations. The ground conditions, including type of soils and rocks, unit thickness, rock strength and defects, and groundwater condition, are unique for each site.

Dilapidation survey of adjoining properties and road infrastructure should be carried out prior to commencement of construction.

To achieve the required vibration limits, the operating limits of the maximum capacity for different types of rock excavation plants and distance to nearest structures are provided in Table 7 overleaf as a guidance.

	Maximum Peak Particle Velocity (PPV)				
Distance from adjoining	PPV=	= 5mm/sec	PPV=10mm/sec		
structure (m)	Plant	Operating Limit (% of Maximum Capacity)	Plant	Operating Limit (% of Maximum Capacity)	
1.5 to 2.5	Hand operated Jack Hammer	50	Hand operated Jack Hammer	100	
	Rock saw on excavator	50	Rock saw on excavator	100	
2.5 to 5.0	Ripper on 20 tonne excavator	50	300kg Rock Hammer	100	
	300kg Rock Hammer	50	600kg Rock Hammer	50	
5.0 to 10.0	300kg Rock Hammer	100	600kg Rock Hammer	100	
5.0 10 10.0	600kg Rock Hammer	50	900kg Rock Hammer	50	

Table 7 - Preliminary Vibration Limits related to Buffer Distance and Type of Plant

Hammering is not recommended and should be avoided. However, if necessary, hammering should be carried out horizontally along bedding planes of (pre-cut) broken rock blocks where possible with noise levels restricted to acceptable to comfortable limits to adjacent residents. To ensure vibration levels remain within acceptable levels and minimise the potential effects of vibration, excavation into medium strength concrete and/or Class IV Sandstone or stronger rock should be carried out in a controlled & careful manner, and complemented with saw cutting or other appropriate methods prior to excavation.

7. CONCLUSIONS AND RECOMMENDATIONS

- Results of geotechnical investigation and assessment indicate ground conditions at this site are suitable for proposed dwellings and associated works.
- Based on proposed development and subsurface conditions, we assessed a footing system consisting of cast-in-situ reinforced concrete shallow foundations are applicable for proposed structures within basement area, while piers/piled foundations can be considered for those structures proposed outside the footprint of basement area. We recommend the suitable founding materials should be Unit 3 "Class V Sandstone" with shale and laminite for any footing systems adopted.

The details of footing systems and recommended geotechnical design parameters are provided in Section 6.5.

- For service pipes or slabs to fully or partially rely on soils underneath (either existing fill or new fill), "Foundation/subgrade Preparation" in Section 6.6 should be implemented during construction.
- The construction, fill & compaction, earthworks, excavation methods and vibration control measures, safe excavation batters, excavation support/shoring measures, retaining walls, footing system, foundation/subgrade preparation, drainage works, and water/seepage management should be implemented in accordance with the recommendations provided in Section 6 of this report.
- A Geotechnical Engineer should be engaged to inspect foundation excavations to ensure the foundation base have been taken to suitable materials of appropriate bearing capacity and adequate embedment depth/socket length if unexpected ground conditions are encountered or a geotechnical certificate is required.
- If the recommendations made in this report are adopted during design and construction, the construction of proposed development and excavation over a short and long term will have no impacts on adjoining properties, roads and public infrastructure.

8. LIMITATIONS

This report should be read in conjunction with the "Limitations of Geotechnical Investigation Statement" attached as Appendix E, which provides important information regarding geotechnical investigation, assessment and reporting. If the actual subsurface conditions exposed during construction vary significantly from those discussed in this report, this report should be reviewed and the undersigned should be contacted for further consultation and advices.

Explanatory Notes – Description for Soil

In engineering terms soil includes every type of uncemented or partially cemented inorganic material found in the ground. In practice, if the material can be remoulded by hand in its field condition or in water it is described as a soil. The dominant soil constituent is given in capital letters, with secondary textures in lower case. The dominant feature is assessed from the Unified Soil Classification system and a soil symbol is used to define a soil layer.

METHOD

Mathad	Description
Method	Description
AS	Auger Screwing
BH	Backhoe
CT	Cable Tool Rig
EE	Existing Excavation/Cutting
EX	Excavator
HA	Hand Auger
HQ	Diamond Core-63mm
JET	Jetting
NMLC	Diamond Core –52mm
NQ	Diamond Core –47mm
PT	Push Tube
RAB	Rotary Air Blast
RB	Rotary Blade
RT	Rotary Tricone Bit
TC	Auger TC Bit
V	Auger V Bit
WB	Washbore
DT	Diatube

WATER

NFGWO: The observation of groundwater, whether present or not, was not possible due to drilling water, surface seepage or cave in of the borehole/test pit.

NFGWE: The borehole/test pit was dry soon after excavation. Inflow may have been observed had the borehole/test pit been left open for a longer period.

SAMPLING

Sample	Description
В	Bulk Disturbed Sample
D	Disturbed Sample
Jar	Jar Sample
SPT	Standard Penetration Test
U50	Undisturbed Sample -50mm
U75	Undisturbed Sample –75mm

UNIFIED SOIL CLASSIFICATION

The appropriate symbols are selected on the result of visual examination, field tests and available laboratory tests, such as, sieve analysis, liquid limit and plasticity index.

USC Symbol	Description
GW	Well graded gravel
GP	Poorly graded gravel
GM	Silty gravel
GC	Clayey gravel
SW	Well graded sand
SP	Poorly graded sand
SM	Silty sand
SC	Clayey sand
ML	Silt of low plasticity
CL	Clay of low plasticity
OL	Organic soil of low plasticity
MH	Silt of high plasticity
CH	Clay of high plasticity
OH	Organic soil of high plasticity
Pt	Peaty Soil

MOISTURE CONDITION

Dry - Cohesive soils are friable or powdery Cohesionless soil grains are free-running

Moist - Soil feels cool, darkened in colour Cohesive soils can be moulded Cohesionless soil grains tend to adhere

Wet - Cohesive soils usually weakened

Free water forms on hands when handling

For cohesive soils the following codes may also be used:

MC~PL Moisture Content near the Plastic Limit.	MC>PL	Moisture Content greater than the Plastic Limit
	MC~PL	Moisture Content near the Plastic Limit.
MC <pl content="" less="" limit.<="" moisture="" plastic="" td="" than="" the=""><td>MC<pl< td=""><td>Moisture Content less than the Plastic Limit.</td></pl<></td></pl>	MC <pl< td=""><td>Moisture Content less than the Plastic Limit.</td></pl<>	Moisture Content less than the Plastic Limit.

PLASTICITY

The potential for soil to undergo change in volume with moisture change is assessed from its degree of plasticity. The classification of the degree of plasticity in terms of the Liquid Limit (LL) is as follows:

Description of Plasticity	LL (%)
Low	<35
Medium	35 to 50
High	>50

COHESIVE SOILS - CONSISTENCY

The consistency of a cohesive soil is defined by descriptive terminology such as very soft, soft, firm, stiff, very stiff and hard. These terms are assessed by the shear strength of the soil as observed visually, by hand penetrometer values and by resistance to deformation to hand moulding.

A Hand Penetrometer may be used in the field or the laboratory to provide an approximate assessment of the unconfined compressive strength (UCS) of cohesive soils. The undrained shear strength of cohesive soils is approximately half the UCS. The values are recorded in kPa as follows:

Strength	Symbol	Undrained Shear Strength, C _u (kPa)
Very Soft	VS	< 12
Soft	S	12 to 25
Firm	F	25 to 50
Stiff	St	50 to 100
Very Stiff	VSt	100 to 200
Hard	Н	> 200

COHESIONLESS SOILS - RELATIVE DENSITY

Relative density terms such as very loose, loose, medium, dense and very dense are used to describe silty and sandy material, and these are usually based on resistance to drilling penetration or the Standard Penetration Test (SPT) 'N' values. Other condition terms, such as friable, powdery or crumbly may also be used.

Term	Symbol	Density Index	N Value
			(blows/0.3 m)
Very Loose	VL	0 to 15	0 to 4
Loose	L	15 to 35	4 to 10
Medium Dense	MD	35 to 65	10 to 30
Dense	D	65 to 85	30 to 50
Very Dense	VD	>85	>50

COHESIONLESS SOILS PARTICLE SIZE DESCRIPTIVE TERMS

Name	Subdivision	Size
Boulders		>200 mm
Cobbles		63 mm to 200 mm
Gravel	coarse	20 mm to 63 mm
	medium	6 mm to 20 mm
	fine	2.36 mm to 6 mm
Sand	coarse	600 µm to 2.36 mm
	medium	200 µm to 600 µm
	fine	75 μm to 200 μm

Description for Rock

The rock is described with strength and weathering symbols as shown below. Other features such as bedding and dip angle are given.

METHOD

Refer soil description sheet

WATER

Refer soil description sheet

ROCK QUALITY

The fracture spacing is shown where applicable and the Rock Quality Designation (RQD) or Total Core Recovery (TCR) is given where:

TCR (%) =	<u>length of core recovered</u> length of core run	
RQD (%) =	Sum of Axial lengths of core > 100mm long	

length of core run

ROCK MATERIAL WEATHERING

Rock weathering is described using the abbreviations and definitions used in AS1726. AS1726 suggests the term "Distinctly Weathered" (DW) to cover the range of substance weathering conditions between (but not including) XW and SW. For projects where it is not practical to delineate between HW and MW or it is deemed that there is no advantage in making such a distinction, DW may be used with the definition given in AS1726.

Symbol	Term	Definition
RS	Residual Soil	Soil definition on extremely weathered rock; the mass structure and substance are no longer evident; there is a large change in volume but the soil has not been significantly transported
XW	Extremely Weathered	Rock is weathered to such an extent that it has 'soil' properties, ie. It either disintegrates or can be remoulded in water
HW $\Big DW$	Highly Weathered Distinctly Weathered (see AS1726 Definition below)	The rock substance is affected by weathering to the extent that limonite staining or bleaching affects the whole rock substance and other signs of chemical or physical decomposition are evident. Porosity and strength is usually decreased compared to the fresh rock. The colour and strength of the fresh rock is no longer recognisable.
MW	Moderately Weathered	The whole of the rock substance is discoloured, usually by iron staining or bleaching, to the extent that the colour of the fresh rock is no longer recognisable
SW	Slightly Weathered	Rock is slightly discoloured but shows little or no change of strength from fresh rock
FR	Fresh	Rock shows no sign of decomposition or staining

"Distinctly Weathered: Rock strength usually changed by weathering. The rock may be highly discoloured, usually by iron staining. Porosity may be increased by leaching, or may be decreased due to the deposition of weathering products in pores." (AS1726)

ROCK STRENGTH

Rock strength is described using AS1726 and ISRM - Commission on Standardisation of Laboratory and Field Tests, "Suggested method of determining the Uniaxial Compressive Strength of Rock materials and the Point Load Index", as follows:

Term	Symbol	Point Load Index Is ₍₅₀₎ (MPa)
Extremely Low	EL	< 0.03
Very Low	VL	0.03 to 0.1

Low	L	0.1 to 0.3
Medium	М	0.3 to 1
High	Н	1 to 3
Very High	VH	3 to 10
Extremely High	EH	>10

- Diametral Point Load Index test
- Axial Point Load Index test

DEFECT SPACING/BEDDING THICKNESS

Measured at right angles to defects of same set or bedding.

Term	Defect Spacing	Bedding
Extremely closely spaced	<6 mm	Thinly Laminated
	6 to 20 mm	Laminated
Very closely spaced	20 to 60 mm	Very Thin
Closely spaced	0.06 to 0.2 m	Thin
Moderately widely spaced	0.2 to 0.6 m	Medium
Widely spaced	0.6 to 2 m	Thick
Very widely spaced	>2 m	Very Thick

DEFECT DESCRIPTION

Туре:	Definition:
В	Bedding
BP	Bedding Parting
F	Fault
С	Cleavage
J	Joint
SZ	Shear Zone
CZ	Crushed Zone
DB	Drill Break

Planarity:	Roughness:	
P – Planar	R – Rough	
Ir – Irregular	S – Smooth	
St - Stepped	S1 – Slickensides	
U – Undulating	Po-Polished	

Coating or Infill:	Description
Clean	No visible coating or infilling
Stain	No visible coating or infilling but surfaces are
Veneer	discoloured by mineral staining A visible coating or infilling of soil or mineral substance but usually unable to be measured (<1mm).
Coating	If discontinuous over the plane, patchy veneer A visible coating or infilling of soil or mineral substance, >1mm thick. Describe composition and thickness

The inclinations of defects are measured from perpendicular to the core axis.

2

Graphic Symbols for Soil and Rock

Graphic symbols used on borehole and test pit reports for soil and rock are as follows. Combinations of these symbols may be used to indicate mixed materials such as clayey sand.

Engineering classification of shales and sandstones in the Sydney Region - A summary guide

The Sydney Rock Class classification system is based on rock strength, defect spacing and allowable seams as set out below. All three factors must be satisfied.

CLASSIFICATION FOR SANDSTONE

Class	Uniaxial Compressive Strength (MPa)	Defect Spacing (mm)	Allowable Seams (%)
Ι	>24	>600	<1.5
Π	>12	>600	<3
III	>7	>200	<5
IV	>2	>60	<10
V	>1	N.A.	N.A.

CLASSIFICATION FOR SHALE

Class	Uniaxial Compressive Strength (MPa)	Defect Spacing (mm)	Allowable Seams (%)
Ι	>16	>600	<2
II	>7	>200	<4
III	>2	>60	<8
IV	>1	>20	<25
V	>1	N.A.	N.A.

1. ROCK STRENGTH

For expedience in field/construction situations the uniaxial (unconfined) compressive strength of the rock is often inferred, or assessed using the point load strength index (Is_{50}) test (AS 4133.4.1 - 1993). For Sydney Basin sedimentary rocks the uniaxial compressive strength is typically about 20 x (Is_{50}) but the multiplier may range from about 10 to 30 depending on the rock type and characteristics. In the absence of UCS tests, the assigned Sydney Rock Class classification may therefore include rock strengths outside the nominated UCS range.

2. DEFECT SPACING

The terms relate to spacing of natural fractures in NMLC, NQ and HQ diamond drill cores and have the following definitions:

Defect Spacing (mm)	Terms Used to Describe Defect Spacing ¹		
>2000	Very widely spaced Widely spaced Moderately spaced Closely spaced Very closely spaced Extremely closely spaced		
600 - 2000			
200 - 600			
60 - 200			
20 - 60			
<20			

¹After ISO/CD14689 and ISRM.

3. ALLOWABLE SEAMS

Seams include clay, fragmented, highly weathered or similar zones, usually sub-parallel to the loaded surface. The limits suggested in the tables relate to a defined zone of influence. For pad footings, the zone of influence is defined as 1.5 times the least footing dimension. For socketed footings, the zone includes the length of the socket plus a further depth equal to the width of the footing. For tunnel or excavation assessment purposes the defects are assessed over a length of core of similar characteristics.

LIMITATIONS OF GEOTECHNICAL INVESTIGATION

ESWNMAN 25 YEARS EXPERIENCE

© ESWNMAN Pty Ltd

General

In making an assessment of a site from a limited number of boreholes or test pits there is the possibility that variations may occur between testing locations. Site exploration identifies specific subsurface conditions only at those points from which samples have been taken. The risk that variations will not be detected can be reduced by increasing the frequency of testing locations. The investigation program undertaken is a professional estimate of the scope of investigation required to provide a general profile of the subsurface conditions. The data derived from the site investigation program and subsequent laboratory testing are extrapolated across the site to form an inferred geological model and an engineering opinion is rendered about overall subsurface conditions and their likely behaviour with regard to the proposed development. Despite investigation the actual conditions at the site might differ from those inferred to exist, since no subsurface exploration program, no matter how comprehensive, can reveal all subsurface details and anomalies.

The borehole/test pit logs are the subjective interpretation of subsurface conditions at a particular location, made by trained personnel. The interpretation may be limited by the method of investigation, and cannot always be definitive.

Subsurface conditions

Subsurface conditions may be modified by changing natural forces or man-made influences. A geotechnical report is based on conditions which existed at the time of subsurface exploration.

Construction operations at or adjacent to the site, and natural events such as rainfall events, floods, or groundwater fluctuations, may also affect subsurface conditions, and thus the continuing adequacy of a geotechnical report. The geotechnical engineer should be kept appraised of any such events, and should be consulted to determine if additional tests are necessary.

Assessment and interpretation

A geotechnical engineer should be retained to work with other appropriate design professionals explaining relevant geotechnical findings and in reviewing the adequacy of their drawings/plans and specifications relative to geotechnical issues.

Information and documentations

Final logs are developed by geotechnical engineers based upon their interpretation of field description and laboratory results of field samples. Customarily, only the final logs are included in geotechnical engineering reports. These logs should not under any circumstances be redrawn for inclusion in architectural or other design drawings. To minimise the likelihood of bore/profile log misinterpretation, contractors should be given access to the complete geotechnical engineering report prepared or authorised for their use. Providing the best available information to contractors helps prevent costly construction problems.

Construction phase service (CPS)

During construction, excavation is frequently undertaken which exposes the actual subsurface conditions. For this reason geotechnical consultants should be retained through the construction stage, to identify variations if they are exposed and to conduct additional tests which may be required and to deal quickly with geotechnical problems if they arise.

ESWNMAN does not accept any liability for site conditions not observed during the time of the construction or inspection.

Report

The report has been prepared for the benefit of the client and no other parties. ESWNMAN PTY LTD assumes no responsibility and will not be liable to any other person or organisation for or in relation to any matter dealt with or conclusions expressed in the report, or for any loss or damage suffered by any other person or organisation arising from matters dealt with or conclusions expressed in the report (including without limitation matters arising from any negligent act or omission of ESWNMAN PTY LTD or for any loss or damage suffered by any other party relying upon the matters dealt with or conclusions expressed in the report). Other parties should not rely upon the report or the accuracy or completeness of any conclusions and should make their own enquiries and obtain independent advice in relation to such matters.

Other limitations

ESWNMAN PTY LTD will not be liable to update or revise the report to take into account any events or emergent circumstances or facts occurring or becoming apparent after the date of the report.
