Water Cycle Management

1 INTRODUCTION

Brown Consulting has been engaged by White Constructions Pty Ltd to prepare the Water Cycle Management for Cedar Grove Estate stage 2 to support the rezoning application.

The site is located in Kiama, NSW. Cedar Grove Stage 2 is located south of the Stage 1 development and bounded to the east by Willow Gully Creek and rural properties to the west. The site drains to Willow Gully Creek with a portion of the western catchments discharge into Spring Creek. The Northern catchments drain to the Cedar Grove Stage I basins (basin I & 2), refer to figure 2.

Figure 1 Locality Sketch

1.1 OBJECTIVES

The water cycle management report aims to provide a stormwater strategy suitable for the rezoning of stage 2 Cedar Grove Estates. The report provides a stormwater strategy that is suitable for managing stormwater quantity and quality for a proposed development. Greater detail will be provided during the various design phases.

2 HYDROLOGY

The stormwater masterplan undertaken for Cedar Grove Estate stage I (Brown, 2004) reported on the hydrological modelling of Willow Gully Creek. The study established that the catchments that drain directly to Willow Gully Creek did not require OSD due to the lag time associated with the upstream Catchment. The study showed that development conditions with no OSD did not impact the peak flows in Willow Gully Creek because of the close location to the creek outlet, the Ocean.

Basin I within Stage I Cedar Grove, provided OSD detention for the developed catchment to ensure no aggravating of flows within Spring Creek. The design of basin I and 2 included receiving flows from a portion of the existing stage 2 catchments.

3 DETENTION

The Kiama Municipal Council Water Sensitive Urban Design Policy identifies the On-site retention/ Onsite detention requirements for a development. Where rainwater tanks are over 5000 litres and utilised for toilets, laundry and external uses, Council will allow 40% of the rainwater tank volume to be credited to OSD.

3.1 Catchments Draining to Willow Gully Creek

The catchments draining directly to Willow Gully Creek are close to the ocean outlet and will not provide OSD to avoid aligning peak flood levels with the upstream Creek catchments. The lots will provide rainwater tanks for reuse (2000-3000 L) and manage environmental flows, for larger events the flows will discharge directly into Willow Gully Creek.

3.2 Catchments Draining to Cedar Grove Stage 1 Basin 1

Cedar Grove Estate Stage I provided detention storage for all storms up to the 100 year ARI storm event, and included the existing catchment upstream of the developed (stage 2). The proposal for stage 2 Cedar Grove reduces the catchment area draining to the constructed stage I basin I, and therefore a proportion of the storage within the stage I basin can be utilised to manage the flows off stage 2.

Furthermore the lots within Stage 2 will provide rainwater tanks with a detention component that will ensure no aggravating of flows at the stage 1 basin outlet.

3.3 Catchments Draining to Cedar Grove Stage 1 Basin 2

Cedar Grove Estate Stage I study established that the catchment area draining to basin 2 did not require stormwater detention to ensure peak flood levels downstream were not aggravated as a result of the development. A portion of the stage 2 development is included in the basin 2 catchment area, and will not require On-site detention.

The stage 2 development will include rainwater tanks that will manage environmental flows, but will not require detention for the major storm events due to the close proximity to the Ocean.

3.4 Catchments Draining Directly to Spring Creek

The catchments along the western boundary drain directly to Spring Creek and will provide stormwater detention. The Kiama Municipal Council Water Sensitive Urban Design Policy identifies a site storage requirement of 132 m³/ha and permissible site discharge of 600 L/s/ha. Where rainwater tanks are over 5000 litres and utilised for toilets, laundry and external uses, 40% of the rainwater tank volume to be credited to OSD, and the remainder of storage shortfall could be contained within the air gap of the rainwater tank or elsewhere within the lot. Alternatively the OSD component can be contained within a basin downstream of the development prior to discharging into Spring Creek. The proposed lot configuration and detention strategy is subject to detailed design.

4 WATER QUALITY

The Kiama Municipal Council Water Sensitive Urban Design Policy identifies the pollutant removal targets, the targets are as follows;

Pollutant	Target (% Removal)
Total Suspended Solids (TSS)	80
Total Nitrogen (TN)	45
Total Phosphorus (TP)	45

The Cedar Grove Stage I developed a treatment train to utilise gross pollutant traps and biofiltration basins for treatment of minor storm events (approximately 3 month ARI). The Stage I bio-filtration basin filter surface areas are as follows:

- Basin I 250 m²
- Basin 2 385 m²

The results water quality treatment devices showed a significant reduction in developed loads, 91% reduction in suspended solids, 53% reduction in total nitrogen and 63% reduction in total phosphorous.

Preliminary water quality modelling of a proposed development located at Stage 2 Cedar Grove has been undertaken using the Model for Urban Stormwater Improvement Conceptualisation (MUSIC) software package developed by the Cooperative Research Centre for Catchment Hydrology (CRCCH). MUSIC enables the user to model the transfer of pollutants through a catchment and provides an aid in determining the treatment strategy required to meet the water quality objectives applicable to the site. The critical pollutants to be modelled are Gross Pollutants, Total Nitrogen (TN), Total Phosphorous (TP) and Total Suspended Solids (TSS).

The generation, transfer and removal of these critical pollutants will be modelled through a proposed treatment strategy. Only the critical pollutants will be further addressed in this report, however the treatment devices will provide mitigation of other pollutant loads, such as heavy metals, since they are predominantly associated with fine sediment. The Primary Pollutant trap will intercept pollutants such as litter, rubbish, leaves etc therefore minimising the runoff of oxygen demanding substances.

4.1 Catchments Draining to Willow Gully Creek

The catchments draining directly to Willow Gully Creek will utilise rainwater tanks within each lot and bioretention swales. Preliminary modelling suggests a bioretention area of 120 m^2 (northern outlet) and

40 m² (southern outlet) would be required throughout the catchment, the bioretention can be provided within each lot, within open space or swales within the road corridors.

4.2 Catchments Draining to Cedar Grove Stage 1 Basin 1

The catchment areas draining to basin I stage I utilises the bioretention within the basin. Furthermore the stage 2 lots within the catchment will provide rainwater tanks, and a vegetated buffer strip is located along the boundary upstream of stage I for further treatment.

4.3 Catchments Draining to Cedar Grove Stage 1 Basin 2

The catchment areas draining to basin 2 stage I utilises the bioretention within the basin. Furthermore the stage 2 lots within the catchment will provide rainwater tanks, and a vegetated buffer strip is located along the boundary upstream of stage I for further treatment.

4.4 Catchments Draining Directly to Spring Creek

The catchments draining directly to Spring Creek will utilise rainwater tanks within each lot and bioretention swales. Preliminary modelling suggests a bioretention area of 80 m² would be required throughout the catchment to meet the removal targets, the bioretention can be provided within each lot, open space areas or swales within the road corridors. Alternatively the bioretention can be contained within a basin located downstream of the lots prior to discharging into Spring Creek.

4.5 Removal Efficiencies

Preliminary MUSIC modelling for the rezoning of stage 2 Cedar Grove Estates shows the water quality treatment strategy proposed above will achieve the following pollutant removal ;

Pollutant	Inflow (kg/yr)	Outflow (kg/yr)	% Removal	Achieved Target
Total Suspended Solids (TSS)	16400	3130	80.9	Yes
Total Nitrogen (TN)	35.4	10.8	69.5	Yes
Total Phosphorus (TP)	269	144	46.5	Yes
Gross Pollutants (GP)	2260	0	100	Yes

5 CONCLUSION

The stormwater management for the rezoning of Cedar Grove Stage 2 has been prepared in accordance with the Kiama Municipal Council Water Sensitive Urban Design Policy (2005). The stormwater components of the development of the land would be designed to meet the principal including;

- Ensuring peak flows are maintained at a rate not exceeding existing conditions,
- Improve water quality of stormwater discharging from the site such that pollutant loads are no worse than existing conditions and meet the removal targets specified by Council,
- Manage environmental flows of Spring Creek and Willow Gully Creek, and
- Promote Water Sensitive Urban Design.

The stormwater management is a conceptual plan for the rezoning, the proposal will be reviewed and detailed for the development application when further details of the subdivision are available.

7 GLOSSARY OF TERMS

Afflux	The rise in water level upstream of a hydraulic structure such as a bridge or culvert, caused by losses incurred from the hydraulic structure
Australian Height Datum	National survey datum corresponding approximately to mean sea level
Appual Exceedance Probability	The change of a flood of a given size or larger occurring in any one year
Annual Exceedance Frobability	The chance of a flood of a given size of larger occurring in any one year,
	ADL C 100 AED C 100 AED C 100 Year
	ARI flood is a 1% AEP flood. An important implication is that when a
	1% AEP flood occurs, there is still a 1% probability that it could occur the
	tollowing year.
Average Recurrence Interval	Is the long term average number of years between the occurrence of a
	flood as big as, or larger than the selected flood event.
Catchment	The catchment at a particular point is the area of land which drains to that
	point.
Design floor level	The minimum (lowest) floor level specified for a building.
Design flood	A hypothetical flood representing a specific likelihood of occurrence (for
	example the 100 year or 1% probability flood). The design flood may
	comprise two or more single source dominated floods.
Development	Existing or proposed works which may or may not impact upon flooding.
*	Typical works are filling of land, and the construction of roads, floodways
	and buildings.
Discharge	The rate of flow of water measured in terms of volume over time. It is
	not the velocity of flow which is a measure of how fast the water is
	moving rather than how much is moving. Discharge and flow are
	interchangeable
Digital Terrain Model	A three dimensional model of the ground surface that can be represented
Digital Terrain Model	A unce-dimensional model of the ground surface that can be represented
	as a series of grids with each cen representing an elevation (DEM) of a
Effective management	The encluded that a comparison of the form manipulation of the demonstration of the demonstra
Effective warning time	The available time that a community has from receiving a flood warning to
	when the flood reaches their location.
First Flush	The initial surface runoff of a rainstorm. During this phase, water
	pollution in areas with high proportions of impervious surfaces is typically
	more concentrated compared to the remainder of the storm.
Flood	Above average river or creek flows which overtop banks and inundate
	floodplains.
Flood awareness	An appreciation of the likely threats and consequences of flooding and an
	understanding of any flood warning and evacuation procedures.
	Communities with a high degree of flood awareness respond to flood
	warnings promptly and efficiently, greatly reducing the potential for
	damage and loss of life and limb. Communities with a low degree of flood
	awareness may not fully appreciate the importance of flood warnings and
	flood preparedness and consequently suffer greater personal and
	economic losses.
Flood behaviour	The pattern / characteristics / nature of a flood.

Flooding	The State Emergency Service uses the following definitions in flood warnings:
	Minor flooding: causes inconvenience such as closing of minor roads and the
	submergence of low level bridges
	Moderate flooding: low-lying areas inundated requiring removal of stock
	and/or evacuation of some houses. Main traffic bridges may be covered.
	Major flooding: extensive rural areas are flooded with properties, villages and
	towns isolated and/or appreciable urban areas are flooded.
Flood frequency analysis	An analysis of historical flood records to determine estimates of design
· · · · · · · · · · · · · · · · · · ·	flood flows.
Flood fringe	Land which may be affected by flooding but is not designated as a
	floodway or flood storage.
Flood hazard	The potential threat to property or persons due to flooding.
Flood level	The height or elevation of flood waters relative to a datum (typically the
	Australian Height Datum). Also referred to as "stage".
Flood liable land	Land inundated up to the probable maximum flood – flood prone land.
Floodplain	Land adjacent to a river or creek which is inundated by floods up to the
	probable maximum flood that is designated as flood prone land.
Flood Planning Levels	Are the combinations of flood levels and freeboards selected for planning
<u> </u>	purposes to account for uncertainty in the estimate of the flood level.
Flood proofing	Measures taken to improve or modify the design, construction and
	alteration of buildings to minimise or eliminate flood damages and threats
	to life and limb.
Floodplain Management	The coordinated management of activities which occur on flood liable
	land.
Floodplain Management Manual	A document by the NSW Government (2001) that provides a guideline for
	the management of flood liable land. This document describes the
	process of a floodplain risk management study.
Flood source	The source of the flood waters.
Floodplain Management	A set of conditions and policies which define the benchmark from
Standard	which floodplain management options are compared and assessed.
Flood standard	The flood selected for planning and floodplain management activities.
	The flood may be an historical or design flood. It should be based on an
	understanding of the flood behaviour and the associated flood hazard. It
	should also take into account social, economic and ecological
	considerations.
Flood storages	Floodplain areas which are important for the temporary storage of flood
	waters during a flood.
Floodways	Those areas of the floodplain where a significant discharge of flow occurs
	during floods. They are often aligned with naturally defined channels.
	Floodways are areas that, even if they are partially blocked, would cause
	significant redistribution of flood flows, or a significant increase in flood
	levels.

Water Cycle Management Cedar Grove Estate Stage 2 Prepared for White Constructions Pty Ltd

Freeboard	A factor of safety usually expressed as a height above the flood standard. Freeboard tends to compensate for the factors such as wave action,
Geographical Information System	A form of computer software developed for mapping applications and data storage. Useful for generating terrain models and processing data for input into flood estimation models.
High hazard	Danger to life and limb; evacuation difficult; potential for structural damage, high social disruption and economic losses. High hazard areas are those areas subject to a combination of flood depth and flow velocity that are deemed to cause the above issues to persons or property.
Historical flood	A flood which has actually occurred – Flood of Record.
Hydraulic	The term given to the study of water flow in rivers, estuaries with coastal systems.
Hydrograph	A graph showing how a river or creek's discharge changes with time.
Hydrology	The term given to the study of the rain-runoff process in catchments.
Low hazard	Flood depths and velocities are sufficiently low that people and their possessions can be evacuated.
Management plan	A clear and concise document, normally containing diagrams and maps, describing a series of actions that will allow an area to be managed in a coordinated manner to achieve defined objectives.
Map Grid Australia	A national coordinate system used for the mapping of features on a representation of the earths surface. Based on the geographic coordinate system 'Geodetic Datum of Australia 1994'.
Peak flood level, flow or velocity	The maximum flood level, flow or velocity occurring during a flood event.
Probable Maximum Flood	An extreme flood deemed to be the maximum flood likely to occur at a particular location.
Probable Maximum Precipitation	The greatest depth of rainfall for a given duration meteorologically possible over a particular location. Used to estimate the probable maximum flood.
Probability	A statistical measure of the likely frequency or occurrence of flooding.
Riparian Zone	Areas that are located adjacent to watercourses. Their definition is vague and can be characterised by landform, vegetation, legislation or their function.
Runoff	The amount of rainfall from a catchment which actually ends up as flowing water in the river of creek.
Stage	Equivalent to water level above a specific datum- see flood level.
Stage hydrograph	A graph of water level over time.
Triangular Irregular Network	A mass of interconnected triangles used to model three-dimensional surfaces
	such as the ground (see DTM) and the surface of a flood.
Velocity	The speed at which the flood waters are moving. Typically, modelled
	velocities in a river or creek are quoted as the depth and width averaged velocity, i.e. the average velocity across the whole river or creek section.
